# Coumarin-Based Receptor for Recognition of $\mathrm{Zn}^{2+}$ Ion: Spectroscopic Evidence and Imaging Application in Living Cells 

Dr. Subarna Guha<br>Faculty of Chemistry, Central Institute of Plastic Engineering and Technology, Haldia, West Bengal, India

#### Abstract

A fluorescent $\mathbf{Z n}^{\mathbf{2 +}}$ sensor 4-Methyl-2, 6-bis (( $\mathbf{2 H} \mathbf{H}$ chromen-2-one) imino) methyl) - phenol (MCP) based on the 6aminocoumarin platform has been synthesized. This sensor acts as a highly sensitive and selective fluorescent ON-OFF probe and strong binding ability towards $\mathbf{Z n}^{2+}$ in DMSO/water 9:1, v/v (100 mM HEPES buffer; pH 7.4) at room temperature. Other common alkali, alkaline earth and transition metal ions have negligible interference. MCP used for bio-medical applications like living cell imaging at physiological pH using a confocal microscope.

Keywords: Fluorescent ON-OFF sensor, $\mathbf{Z n}^{\mathbf{2 +}}$, coumarin, living cells, Theoretical calculations.

## I. INTRODUCTION

As the second most abundant transition-metal ion in the human body, $\mathrm{Zn}^{2+}$ is actively involved in various biological processes [1]. Such as gene transcription, regulation of metalloenzymes, and neural signal transmission [2]. Chelatable $\mathrm{Zn}^{2+}$ is present at especially high concentrations in brain,[3] pancreas,[4] and spermatozoa[5]. Chelatable $\mathrm{Zn}^{2+}$ regulates neuronal transmission in excitatory nerve terminals, suppresses apoptosis,[6] contributes to neuronal injury in certain acute conditions,[7] epilepsy,[8] and transient global ischemia,[9] seizures,[10] and brain injury [11]. In addition to acute toxicity, disruption of $\mathrm{Zn}^{2+}$ homeostasis may play a role in the pathology of several neurodegenerative disorders, [12] like the formation of $\beta$ amyloid plaques in Alzheimer's disease [13-14] ischemic stroke, and infantile diarrhea [15]. In particular, compared to other tissues, pancreatic islets contain relatively high concentrations of $\mathrm{Zn}^{2+}$, which play a critical role in insulin biosynthesis, storage and secretion [16]. Hence, the development of $\mathrm{Zn}^{2+}$-probes is a promising field. Rapid progress has been made in the development of fluorescent $\mathrm{Zn}^{2+}$-probes in solution, due to their simplicity, high sensitivity and instantaneous response and based on ioninduced fluorescence changes [17]. However, reports of their intracellular $\mathrm{Zn}^{2+}$ imaging are rare [18]. It is desired to develop new fluorescent indicators with improved properties, especially with high efficiency in the spectral visible region and study of $\mathrm{Zn}^{2+}$-probes in cell. Most of the currently reported $\mathrm{Zn}^{2+}$ fluorescent sensors have the nature of metal chelation enhanced fluorescence (MCHEF), [19-20] which
functions via $\mathrm{Zn}^{2+}$ binding-induced emission enhancement. Therefore, there is a huge scope and potential for exploring novel fluorophores for $\mathrm{Zn}^{2+}$ sensing.

Although there are many highly effective sensors, most of them often require laborious multistep organic synthesis, which slows the discovery process and causes the prohibitively high cost. While our probe is least expensive as it involves a facile one step reaction with commercially available much cheaper chemicals. Herein we report, the synthesis, and characterization of 6-Amino-coumarin and 2,6 diformyl paracresol hybrid structure (MCP)(Scheme-1), is covalently appended to a $\mathrm{Zn}^{2+}$ sensitive OFF-ON fluorescent behavior both in solution and cell. The reason for the observed fluorescence enhancement is in the absence of $\mathrm{Zn}^{2+}$ ions, the extent of ICT in the ligand MCP is efficient and the fluorescence is effectively quenched. The chelation of MCP with $\mathrm{Zn}^{2+}$ ion induces reduction of the ICT effect in the ligand, thus unquenching the ligand fluorescence. In addition, the enhancement of fluorescence intensity was due to the formation of a MCP. $\mathrm{Zn}^{2+}$ complex, which resulted in the selective CHEF effect. In the presence of $\mathrm{Zn}^{2+}$, the $\mathrm{C}=\mathrm{N}$ conjugation with the phenyl ring is inhibited due to the formation of strong chelation with $\mathrm{Zn}^{2+}$ giving rise to intense fluorescence. On the other hand, in general, compounds containing acyclic $\mathrm{C}=\mathrm{N}$ bonds are nonfluorescent, and cyclic $\mathrm{C}=\mathrm{N}$ bonds significantly fluorescent [21]. 4-Methyl-2, 6-bis (((2H-chromen-2-one) imino) methyl) - phenol (MCP) was designed, in which the $\mathrm{C}=\mathrm{N}$ bond can react with $\mathrm{Zn}^{2+}$ to make the acyclic $\mathrm{C}=\mathrm{N}$ bond become to cyclic $\mathrm{C}=\mathrm{N}$ bond, resulting in a fluorescent product. If a fluorescent chemosensor with low fluorescence intensity (off-type) shows a marked enhancement in fluorescence intensity in presence of $\mathrm{Zn}^{2+}$ (on-type), it is very sensitive for the detection of $\mathrm{Zn}^{2+}$ in living cell. The present synthesis of $\mathrm{Zn}^{2+}$ sensor is aimed so achieving these objectives.

## II. EXPERIMENTAL

### 2.1. Materials

4-Methyl-2, 6-diformylphenol was synthesized starting from p-cresol by following a published procedure [22]. Coumarin was available from S. D. Fine Chem. Ltd., India. 6-
aminocoumarin was synthesized starting from coumarin by following a published procedure [23]. Solvents were purified by standard procedure. All other chemicals and solvents were of analytical reagent grade and were used without further purification. Milli-Q Millipore $18.2 \mathrm{M} \Omega \mathrm{cm}^{-1}$ water was used throughout all the experiments. The sources of $\mathrm{Na}^{+}, \mathrm{Ca}^{2+}, \mathrm{Mn}^{2+}, \mathrm{Cr}^{3+}, \mathrm{Fe}^{3+}, \mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Cd}^{2+}$, $\mathrm{Hg}^{2+}$ and $\mathrm{Pb}^{2+}$ ions are either their chloride, nitrate or perchlorate salts.

### 2.2. Instrumentation

Spectroscopic data were obtained using the following instruments: UV-Vis spectra were recorded on Shimadzu Multi Spec 1501 absorption spectrophotometer; FTIR spectra ( KBr disk, $4000-450 \mathrm{~cm}^{-1}$ ) by Perkin Elmer FT-IR spectrophotometer model RX-1; Mass spectrum was recorded in QTOF Micro YA 263 mass spectrometer in ES positive mode. Fluorescence emission and excitation spectra were recorded at room temperature ( 298 K ) in aqueous solution with a Hitachi F-4500 spectrofluorometer equipped with a temperature controlled cell holder. Micro analytical data (C, H, and N) were collected on Perkin Elmer 2400 CHNS/O elemental analyzer. All pH measurements were performed with systronics digital pH meter (model 335). Thermo gravimetric analysis was performed on a Perkin Elmer TG/DTA lab system 1 (Technology by SII). The fluorescence imaging system was comprised of an inverted fluorescence microscope (Leica DM 1000 LED), digital compact camera (Leica DFC 420C), and an image processor (Leica Application Suite v3.3.0). The microscope was equipped with a mercury 50 watt lamp. The ligand and its $\mathrm{Zn}^{2+}$ complex have been studied theoretically by Ab initio (Hartee Fock) method to have some insight about the MCP- $\mathrm{Zn}^{2+}$ interaction by using Gaussian '03 software package [24].

### 2.3. Synthesis of 4-Methyl-2, 6-bis (((2H-chromen-2-one) imino) methyl) - phenol (MCP)

The compound was prepared by a slight modification of the procedure described previously [25] 4-Methyl-2, 6diformylphenol was synthesized starting from p-cresol by following a published procedure [26]. 6-Aminocoumarine $(0.5 \mathrm{~g}, 6.2 \mathrm{mmol})$ and 2 , 6 diformyl paracresol $(0.254 \mathrm{~g}, 3.1$ mmol) was taken in dry methanol ( 15 cm 3 ) and it was refluxed for 8 hours. The reaction mixture was refluxed for 1 $h$. The solution was filtered, concentrated on a rotaevaporator to dryness. The resulting Schiff base, 4-Methyl-2, 6-bis (( $2 \mathrm{H}-$ chromen-2-one) imino) methyl) - phenol (MCP) is reddish solid. Yield $84 \%$; m.p. $133 \pm 2{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{HNMR}$ ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) (supplementary, Fig.S-1), $\delta: 1.66(\mathrm{~s}, 3 \mathrm{H}), 3.72(\mathrm{~s}, 1 \mathrm{H}), 6.36(\mathrm{~d}$, $2 \mathrm{H}), 6.89(\mathrm{~d}, 2 \mathrm{H}), 7.13(\mathrm{~d}, 2 \mathrm{H}), 7.26(\mathrm{~s}, 2 \mathrm{H}), 7.39(\mathrm{~d}, 2 \mathrm{H}), 7.5(\mathrm{~d}$, 2H), 8.42(s, 2H). QTOF -MS ES+, (supplementary, Fig.S-2) displays two signals of $\mathrm{m} / \mathrm{z} 451$ and 473 , which can be assigned as the signals for $[\mathrm{M}+\mathrm{H}]^{+}$and $[\mathrm{M}+\mathrm{Na}]^{+}$, respectively. FT-IR (supplementary, Fig.S-3) ( $\mathrm{KBr}, \mathrm{v} \mathrm{cm}-1$ ) $v(\mathrm{CO}), \quad 1726 ; \quad v(\mathrm{C}=\mathrm{N}), \quad 1623, \mathrm{UV}-V i s i b l e \quad$ spectrum (supplementary, Fig.S-4) in DMSO/water 9:1, v/v (100 mM

HEPES buffer; pH 7.4 ) solution at $298 \mathrm{~K}\left(\lambda_{\text {max }}, \mathrm{nm}\left(\varepsilon, 10^{3} \mathrm{M}^{-1}\right.\right.$ $\left.\mathrm{cm}^{-1}\right), \quad 246(0.391), \quad 263(0.706), \quad 340(0.031), \quad 372(0.071)$, 382(0.061), 405(0.068). Anal. Calculated for $\mathrm{C}_{27} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{5}$ : C, 71.99; H, 4.03; N, 6.22, Found: C, 71.82.; H, 3.99; N, 6.21.

### 2.4. Synthesis of $M C P-\mathrm{Zn}^{2+}$ complexes

$\mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}(0.025 \mathrm{~g}, 0.084 \mathrm{mmol})$ and MCP $(0.0378 \mathrm{~g}, 0.084$ mmol ) ware taken in a 100 ml round bottom flask dissolved in 20 ml methanol. The mixture was magnetically stirred in air for 6 hr and then refluxed for 25 min whereby a clear solution was formed. On evaporating the solvent the brown colored complex was obtained. The tetra coordination of $\mathrm{Zn}^{2+}$ can be satisfied by one ligand and one nitrate groups. The electrospray ionization QTOF-MS ES+ (supplementary, Fig.S-5) mass spectrum of this complex displays signal of $\mathrm{m} / \mathrm{z}$ 685.07, which can be assigned as the signals for $[\mathrm{M}+\mathrm{Na}]^{+}$. FT-IR (supplementary, Fig.S-6) (KBr, $v \mathrm{~cm}-1) v(\mathrm{C}=\mathrm{O}), 1724$; $v(\mathrm{C}=\mathrm{N}), 1632$, and $v\left(\mathrm{NO}_{3}{ }^{-}\right)$1377. UV-Visible spectrum (supplementary, Fig.S-4) in DMSO/water 9:1, v/v ( 100 mM HEPES buffer; pH 7.4 ) solution at $298 \mathrm{~K}\left(\lambda_{\max }, \mathrm{nm}\left(\varepsilon, 10^{3} \mathrm{M}^{-1}\right.\right.$ $\left.\mathrm{cm}^{-1}\right), \quad 246(0.391), \quad 263(0.706), \quad 340(0.031), \quad 372(0.071)$, 382(0.061), 405(0.068). Anal. Calculated for $\mathrm{C}_{28} \mathrm{H}_{26} \mathrm{~N}_{3} \mathrm{NaO}_{12} \mathrm{Zn}: \mathrm{C}, 49.1 ; \mathrm{H}, 3.83$; $\mathrm{N}, 6.14$, Found: C, 49.04; H, 3.79; N, 6.13.

### 2.5. Measurement procedures

Solutions of $\mathrm{Zn}^{2+}$ and MCP are mixed in different ratios for subsequent fluorescence measurements. The fluorescence emission intensities are measured at 480 nm while the excitation wavelength is fixed at 430 nm .1 .0 cm quartz cell is used for all the measurements.

## III. RESULTS AND DISCUSSION

### 3.1. Spectral characteristics

The metal-binding behavior of MCP has been determined by UV-vis and fluorescence spectroscopic studies. Although MCP is not highly water soluble, it can be dissolved in DMSO/water 9:1, v/v was added and all the following studies were carried out in DMSO/water 9:1, v/v ( 100 mM HEPES buffer; pH 7.4. This protocol is commonly used in many reported $\mathrm{Zn}^{2+}$ sensors for intracellular $\mathrm{Zn}^{2+}$ imaging [27]. The mode of coordination of $\mathbf{M C P}$ with $\mathrm{Zn}^{2+}$ was investigated by spectrophotometric titration at $25^{\circ} \mathrm{C}$ in 100 mM HEPES buffer (pH 7.4). (Supplementary, Fig.S-4) illustrates a typical UV-vis titration curve of MCP with added $\mathrm{Zn}^{2+}$. As can be seen from (Supplementary, Fig.S-4), the absorption intensity of MCP at 230 nm gradually increases as the concentration of $\mathrm{Zn}^{2+}$ increases stepwise. Moreover, a new absorption peak appears at 414 nm in the UV-vis spectrum of the MCP- $\mathrm{Zn}^{2+}$ system, and its intensity also gradually increases with the addition of $\mathrm{Zn}^{2+}$. The presence of a clear isobestic point implies the conversion of free MCP sensor to the only $\mathrm{Zn}^{2+}$ complex. This absorption peak is likely to be due to the coordination of MCP with $\mathrm{Zn}^{2+}$.

The fluorometric titration of ligand $\mathbf{M C P}(10 \mu \mathrm{M})$ in DMSO/water 9:1, v/v ( 100 mM HEPES buffer; pH 7.4 solution exhibits addition of $0.5-20(\mu \mathrm{M})$ concentration of $\mathrm{Zn}^{2+}$ ion (Fig.1). Fig. 2 represents the emission spectra changes of $\mathrm{L}(10 \mu \mathrm{M})$ upon addition of $\mathrm{Zn}^{2+}$ ion. Inset shows the fluorescence image of a solution of the sensors $(10 \mu \mathrm{M})$ with or without $\mathrm{Zn}^{2+}(10 \mu \mathrm{M})$ ion excited by a commercially available UV lamp. The stoichiometry of the (MCP: $\mathrm{Zn}^{2+}=1$ : 1) (Fig.3) of the complex formed between MCP and $\mathrm{Zn}^{2+}$ ion (host and guest) as evaluated by the method of continuous variation (Job's plot), has also been confirmed by mass spectroscopic determination. The fluorescence quantum yield of MCP and $\left[\mathbf{M C P}-\mathrm{Zn}^{2+}\right]$ complex were found to be 0.12 and 0.526 respectively [see ESI for details].

### 3.2. Estimation of binding constant

The unique enhancement of fluorescence is attributed to the strong binding of $\mathrm{Zn}^{2+}$, which is evident from a large binding constant value $\left(2.75 \times 10^{4}\right)$ estimated by modified Benesi-Hildebrand equation [28] (Fig.4).
$(1 / \Delta \mathrm{F})=1 / \Delta \mathrm{F}_{\max }+\left(1 / \mathrm{K}[\mathrm{C}]^{\mathrm{n}}\right)\left(1 / \Delta \mathrm{F}_{\max }\right)$.
Where $\Delta \mathrm{F}=\left(\mathrm{F}_{\mathrm{x}}-\mathrm{F}_{0}\right)$ and $\Delta \mathrm{F}_{\text {max }}=\mathrm{F}_{\infty}-\mathrm{F}_{0}$, where $\mathrm{F}_{0}, \mathrm{~F}_{\mathrm{x}}$, and $\mathrm{F}_{\infty}$ are the emission intensities of $\mathbf{M C P}$ in the absence of $\mathrm{Zn}^{2+}$, at an intermediate $\mathrm{Zn}^{2+}$ concentration, and at the concentration of complete interaction, respectively. K is the binding constant and C is the $\mathrm{Zn}^{2+}$ concentration and n is the number of $\mathrm{Zn}^{2+}$ ion bound per MCP (here, $\mathrm{n}=1$ ).

Fig. 5 showed the plot of variation of emission intensities of MCP as a function of added $\left[\mathrm{Zn}^{2+}\right]$, which could also be used for determination of unknown $\left[\mathrm{Zn}^{2+}\right]$ and also detect as low as $1 \mu \mathrm{M} \mathrm{Zn}^{2+}$ in DMSO/water 9:1, v/v ( 100 mM HEPES buffer; pH 7.4 )solution excited at 430 nm .

Fig. 6 shows the effect of pH on the fluorescence intensity of MCP $(10 \mu \mathrm{M})$ maximum at pH 7.4 , in the presence of 1.0 equiv. of $\mathrm{Zn}^{2+}$ in DMSO/water 9:1, v/v ( 100 mM HEPES buffer; pH 7.4)at room temperature which makes it suitable for biological application in physiological conditions. Fig. 7 showed that the emission intensity of MCP- $\mathrm{Zn}^{2+}$ system in DMSO/water 9:1, v/v ( 100 mM HEPES buffer; pH 7.4) solution remained almost unaltered over a period of 10 minutes.

### 3.3. Selectivity

The influence of a number of common transition metal ions on the fluorescence intensity of the proposed $\left[\mathrm{Zn}^{2+}\right]$ selective chemosensor was investigated (Fig.8).The fluorescence intensity of the complex in the presence of $\mathrm{Zn}^{2+}$ remained either unchanged or weakened (Fig.9) in the presence of alkali, alkaline earth metals $\left(\mathrm{Na}^{+}, \mathrm{Ca}^{2+}\right)$ and small changes with transition metal ions $\left(\mathrm{Cd}^{2+}, \mathrm{Al}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Cr}^{3+}\right.$ $\left.\mathrm{Co}^{2+}, \mathrm{Pb}^{2+},, \mathrm{Ni}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Cu}^{2+}\right)$ which indicate that all these metal ions were not coordinating with the donor site of the title compound MCP.

Stability of the ligand, MCP and its $\mathrm{Zn}^{2+}$ complex was studied by thermogravimetry (TGA/DTG) to prove the binding event of the ligand, MCP with $\mathrm{Zn}^{2+}$ ion supplementary materials (Figs.S-7 and S-8).The TGA curves of the Schiff base complexes were carried out within a temperature range from room temperature up to $700^{\circ} \mathrm{C}$. The thermal decomposition of $\mathrm{Zn}^{2+}$ complexes takes place in several steps as indicated by DTG peaks around $130-170{ }^{\circ} \mathrm{C}$, and $290-330^{\circ} \mathrm{C}$ corresponding to the mass loss of two coordinated water molecules, and nitrate ion, respectively.

### 3.5. Molecular level interaction

The geometry optimizations were carried out using the Ab initio (Hartee Fock) method with a $6-311 \mathrm{G}^{* *}$ basis set for the MCP and LANL2DZ effective core potential (ECP) basis set for the $\mathrm{Zn}^{2+}$ complex is shown in Fig. 10 and Fig. 11 respectively. Distinct differential nature of HOMOs and LUMOs of the MCP and these molecular complexes indicates a molecular level interaction between the ligand L and these metal ions. Fig. 12 MCP showed the energy gap between highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) of the MCP and its complex.

Different parameters like, bond moments, dipole moments, quadruple moments along with optimized energies of the MCP and its complex were presented in the supplementary data (S-9 to S-12).

### 3.6. Preparation and imaging of cells

Candida albicans cells (IMTECH No. 3018) from exponentially growing culture in yeast extract glucose broth medium ( pH 6.0 , incubation temperature, and $37^{\circ} \mathrm{C}$ ) were centrifuged at 3000 rpm for 10 minutes washed twice with 0.1 M HEPES buffer ( pH 7.4 ). Then cells were treated with Zinc nitrate ( $1 \mathrm{mg} / \mathrm{ml}$ ) solution $(10 \mu \mathrm{M})$ for 30 minutes. After incubation, the cells were again washed with HEPES buffer and then incubated with MCP $(10 \mu \mathrm{M})$ for another 15 minutes. Cells thus obtained were mounted on grease free glass slide and then washed in normal saline and photographed under 100X objective using UV filter in a Leica Fluorescence Microscope after adding MCP (Fig.13b). Similarly, freshly collected pollen grains of Allamanda puberula (Aapocynaceae, Fig.13d) have been collected, while their respective controls are presented in Fig.13a and Fig.13c respectively. Cells incubated with MCP but without $\mathrm{Zn}^{2+}$ were used as control. Both $\mathrm{Zn}^{2+}$ treated and untreated cells were stained with MCP and observed under fluorescence microscope.
Photographs indicate that the MCP is easily permeable to the types of living cells tested and harmless (as the cells remain alive even after 30 minutes exposure to the MCP at $10 \mu \mathrm{M}$ concentration). Intensity of the fluorescence is proportional to the concentration of $\mathrm{Zn}^{2+}$ present in the cell. Thus MCP may be used to detect intracellular $\mathrm{Zn}^{2+}$ in living cells.

## IV. CONCLUSIONS

We have demonstrated the synthesis of Schiff base compound an efficient and selective fluorescent sensor for trace level detection and estimation of $\mathrm{Zn}^{2+}$ ion from aqueous solution. The binding of $\mathrm{Zn}^{2+}$ is highly selective, allowing for selective detection in the presence of competitive nontransition and transition-metal ions alike. Preliminary computational studies by ab-initio (Hartree Fock) method provided a molecular level interaction between the reagent (MCP) and $\mathrm{Zn}^{2+}$ ion. Finally, the probe has bio-medical applications like living cell imaging at physiological pH using a confocal microscope.

## ACKNOWLEDGEMENTS

Financial support from Central Institute of Plastic Engineering and Technology, Haldia is gratefully acknowledged.

## SUPPLEMENTARY DATA

Supplementary data absorption, IR, TOF MS, spectra and Theoretical data of physical parameter obtain from Gaussian 03 of MCP \& associated complexes are associated with this article.

Figure. 12 The difference between highest occupied molecular orbital's (HOMO) and lowest unoccupied molecular orbital's (LUMO) of the MCP, and MCP- $\mathrm{Zn}^{2+}$ molecular system.
Figure.13. Fluorescence microscope images of Candida albicans cells (IMTECH No. 3018); pollen grains of Allamanda puberula (Aapocynaceae) without treated with $\mathrm{Zn}^{2+}$ and MCP-stained with $(10 \mu \mathrm{M}) \mathrm{Zn}^{2+}$ for 30 min under 100X objective lens. Incubation was performed at $40^{\circ} \mathrm{C}$.

## Quantum yield measurement

The fluorescence quantum yield of the complex was determined using anthracene as a reference with a known $\phi_{\mathrm{R}}$ value of 0.2 in methanol [1]. The complex and the reference dye were excited at same wavelength ( 430 nm ), maintaining nearly equal absorbance (0.1) and the emission spectra. The area of the emission spectrum was integrated using the software available in the instrument and the quantum yield is calculated according to the following equation:
$\phi_{S} / \phi_{R}=\left[\mathrm{A}_{\mathrm{S}} / \mathrm{A}_{\mathrm{R}}\right] \times\left[(\mathrm{Abs})_{\mathrm{R}} /(\mathrm{Abs})_{\mathrm{S}}\right] \times\left[\eta_{\mathrm{S}}{ }^{2} / \eta_{\mathrm{R}}{ }^{2}\right]$
Here, $\phi_{S}$ and $\phi_{\mathrm{R}}$ were the fluorescence quantum yield of the sample and reference respectively. $A_{S}$ and $A_{R}$ were the area under the fluorescence spectra of the sample and the reference respectively, $(\mathrm{Abs})_{S}$ and $(\mathrm{Abs})_{R}$ were the respective optical densities of the sample and the reference solution at the wavelength of excitation, and $\eta_{S}$ and $\eta_{R}$ are the values of refractive index for the respective solvent used for the sample and reference.
